# 1. Intro

Thank you for purchasing “Dump Truck Controller”!

This package contains all that you need to include a simple and functional dump truck to your game.

More dump truck models may be included in the future and/or sold separately as extensions ([Here](#)).

It's really simple to use and customize.

## 2. How to Use This Asset

In this section you will learn how this asset works and how to use it based on the sample prefabs.

### 2.1. What can it do? (Quick Start Guide)

This asset contains ready to use dump truck prefabs which you can drive and use to move cargo around your game. It also contains a ready to use Rock prefab to be used as cargo.

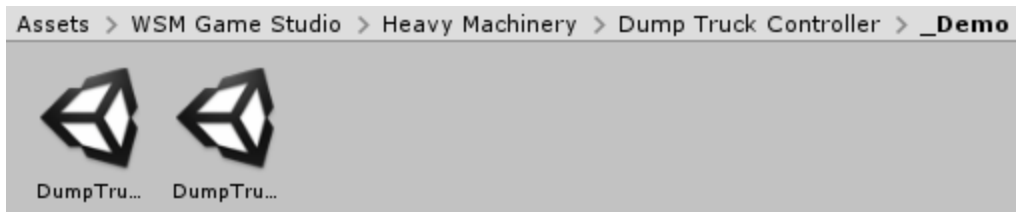

**Figure: Sample Prefabs**

There are 6 dump truck colors by default (yellow, orange, blue, red, black and white), all of which have an old and new texture variation. (albedo, metallic, AO and normal maps included).

**Figure: Brand New x Old Textures Variations**

To see these prefabs in action, please take a look at the demo scene included on the package.

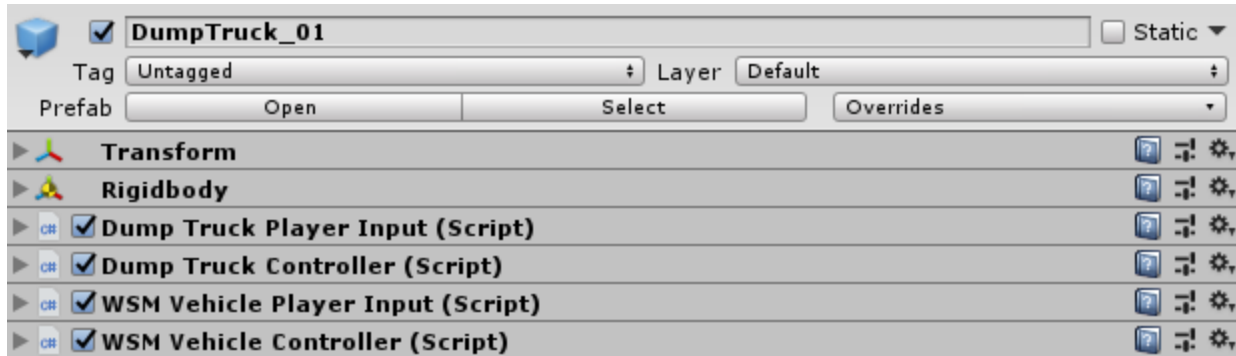

**Figure: Demo Scene**

**Hint:** By pressing the Tab key on the demo scenes you can show or hide the current dump truck input keys. This can be useful for testing the dump truck for the first time.

## 2.2. How it Works

This asset was designed with modularity and easy customization in mind. Therefore, the Component Game Design Pattern was implemented to keep player input, dump truck behaviour and vehicle behaviour as decoupled as possible. Each dump truck is composed of four main modules:

- Dump Truck Player Input
- Dump Truck Controller
- Vehicle Player Input
- Vehicle Controller

**Figure: Dump Truck Components**

The dump truck and vehicle input modules are responsible to gather and feed player input into the corresponding controller modules. For more information about these modules and how to customize input, please take a look at the [Dump Truck Input](#) and [Vehicle Input](#) sections.

The [Dump Truck Controller](#) component is responsible for handling all dump truck specific behaviour. Which means, handling the dump bed and tailgate movements and SFX. For more information, please take a look at the [Dump Truck Controller](#) section.

The [Vehicle Controller](#) component is responsible for handling all vehicle specific behaviour (Ex: acceleration, steering, vehicle physics, etc.). For more information, please take a look at the [Vehicle Controller](#) section.

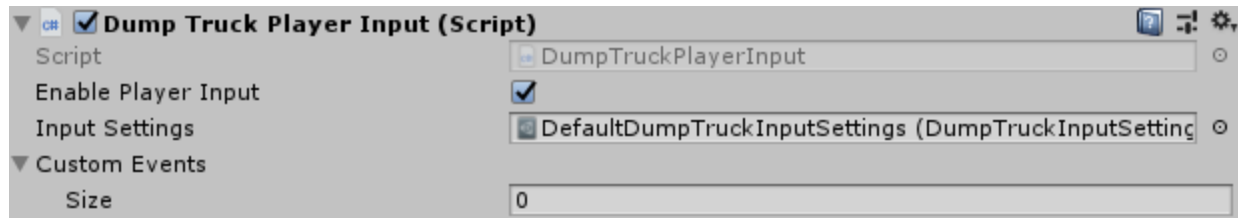

This modular approach was adopted to allow customization by the replacement of any module for third party or custom modules. For example, a client that already owns a custom or third party vehicle controller, may wish to replace the default vehicle related modules and still be able to control the dump truck mechanical parts by using the Dump Truck Controller component.

## 3. Dump Truck Modules

This section covers the dump truck related modules and settings.

### 3.1. Dump Truck Input

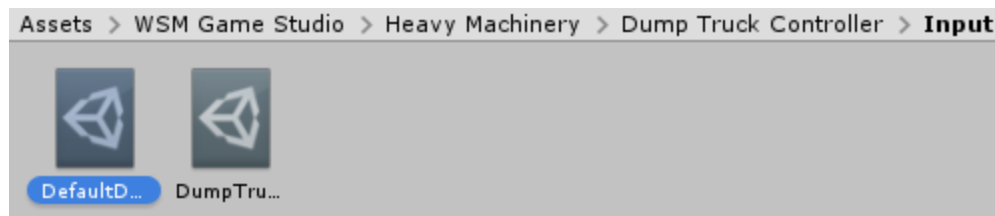

This component is responsible for handling player input for all dump truck specific behaviours. It holds a reference to the Default Dump Trcu Input Settings file, which contains the keyboard key configurations for controlling the mechanical parts of your dump truck.

**Figure: Dump Truck Player Input**

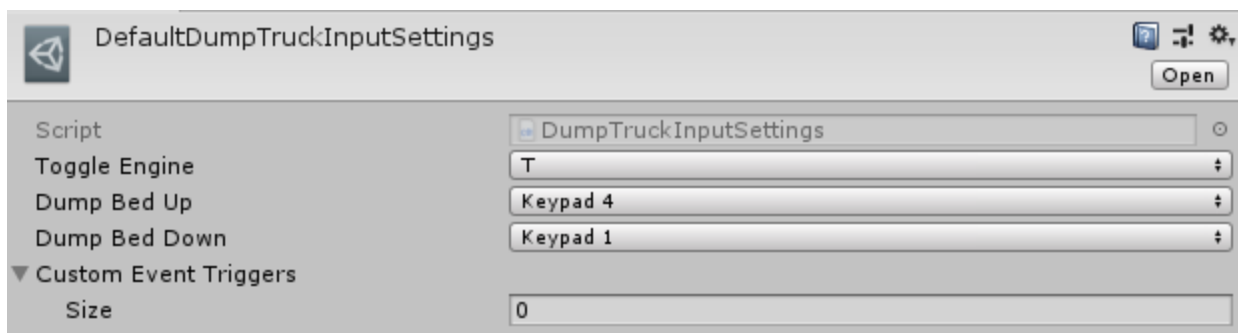

**Note:** Enable Player Input can be used to toggle input on/off.

The Default Dump Truck Input Settings file is located under the “WSM Game Studio ► Heavy Machinery ► Dump Truck Controller ► Input” folder.

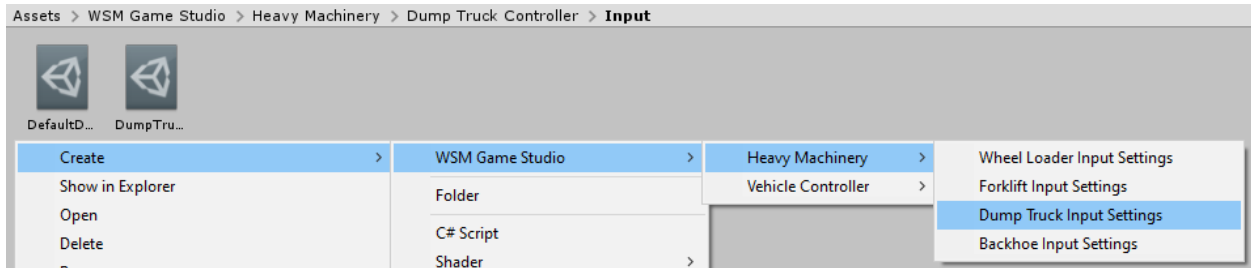

**Figure: Dump Truck Input Settings Location**

By selecting this file, you can see and customize the input keys used to control your dump truck.

**Figure: Dump Truck Input Settings**

You can also create a new custom input settings by right-clicking on your project and using the Unity Creation menu: “Create ► WSM Game Studio ► Heavy Machinery ► Dump Truck Input Settings”.

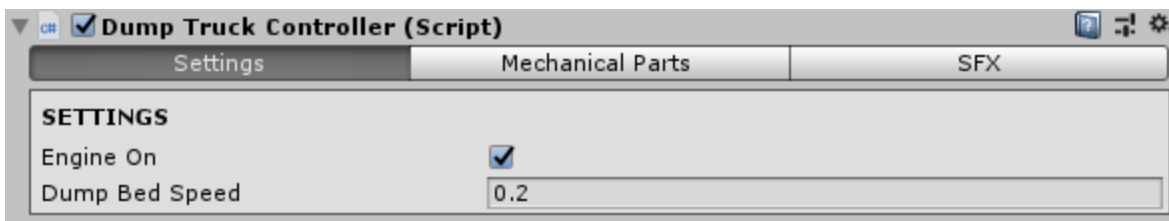

**Figure: Creating a custom Dump Truck Input Settings**

You can create as many input settings as you wish, this can be very useful for testing different input settings for your game.

## 3.2. Dump Truck Controller

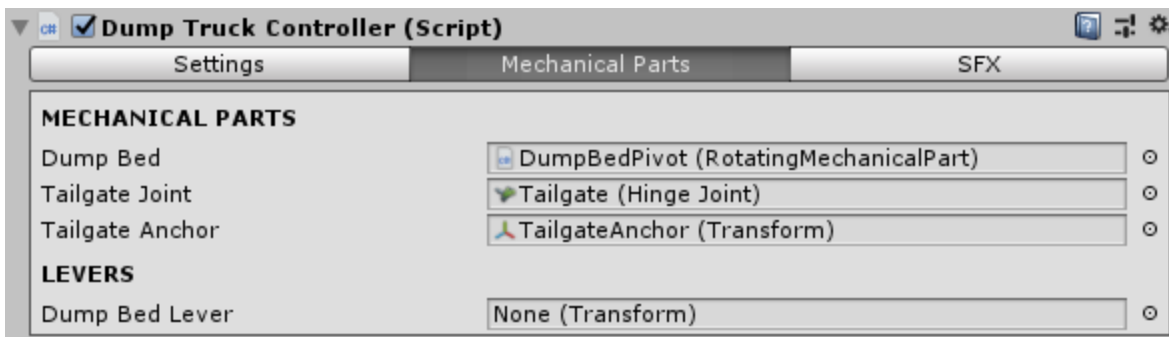

This component is responsible for controlling the dump bed and tailgate mechanical movements.

**Figure: Dump Truck Controller**

At the Settings tab, you can set up the dump bed movement speed and enable or disable the mechanical parts engine.

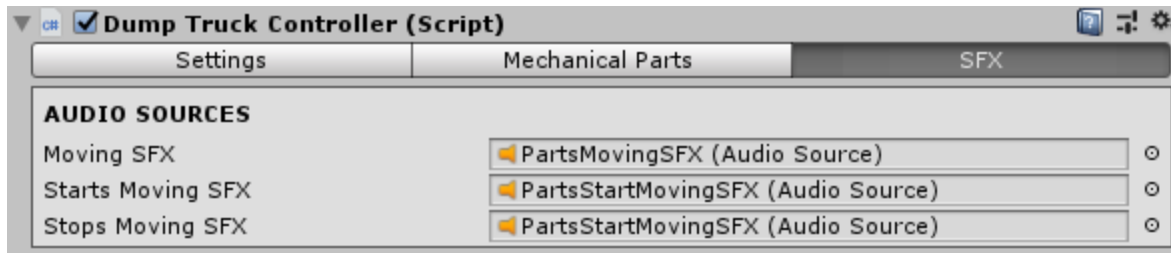

**Note:** The dump truck mechanical parts engine and vehicle engine are separated for the sake of modularity.

**Figure: Dump Truck Mechanical Parts**

The Mechanical Parts tab holds the references to all dump truck mechanical parts.

**Note:** Besides the dump bed and tailgate related mechanical parts, it also supports levers, to simulate the operator manually moving the levers at the cabin.

**Figure: Dump Truck SFX**

The SFX tab holds references to all the mechanical movements related [Audio Sources](#).

### 3.2.1 Tailgate physics

This asset does use the Unity physics engine to simulated tailgate movement.

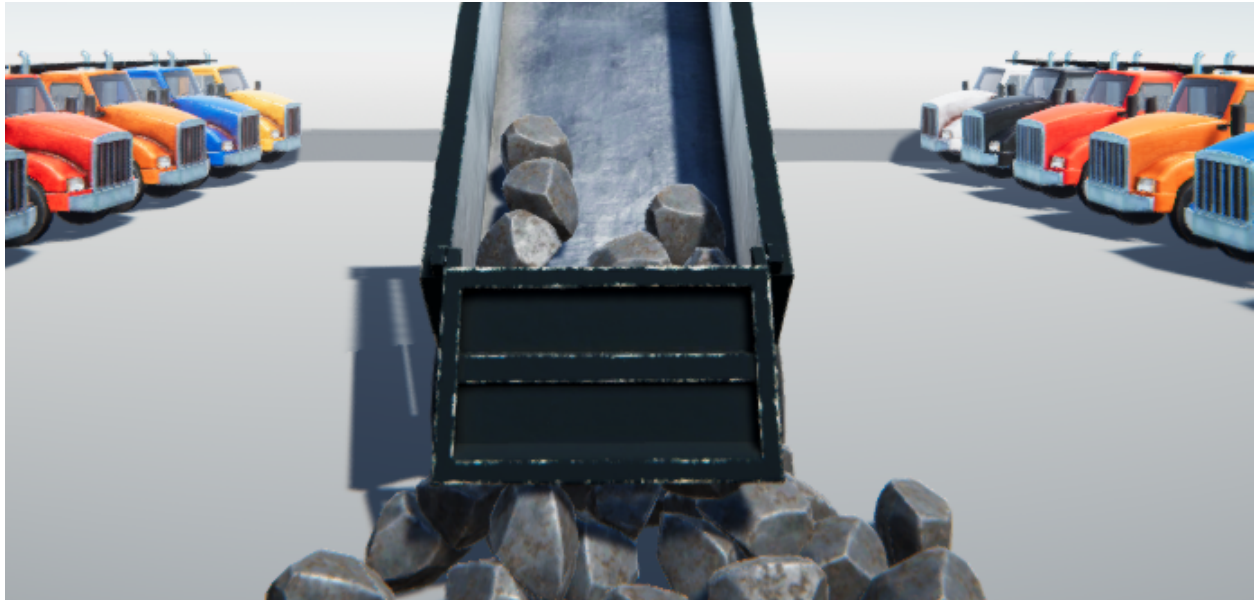

When the dump bed is at its rest position, the tailgate will remain closed and firmly in place. That way, you can safely drive around without losing any cargo. However, once you start raising the dump bed, the tailgate will automatically unlock to allow cargo dumping.

When the tailgate is open, it will physically interact with cargo and will swing back and forward as you move the truck forward and backwards. To lock the tailgate again, you just need to return the dump bed to its rest position.

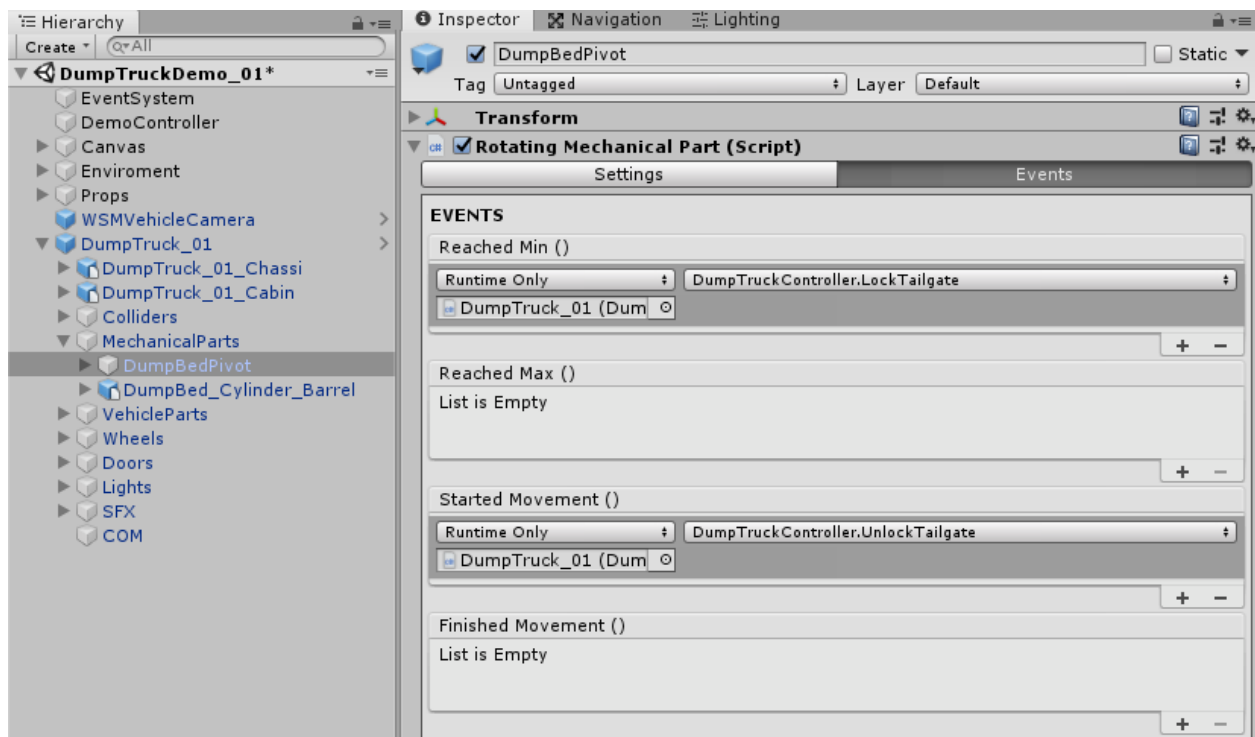

**Figure: Tailgate at rest position (rear view)**

**Figure: Open Tailgate (rear view)**

The tailgate lock and unlocking public methods are located on the Dump Truck Controller component. These methods are triggered by custom events assigned to the dump bed mechanical part component.

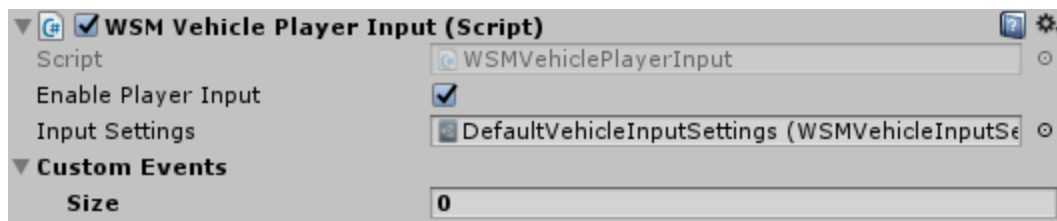

**Figure: Tailgate locking & unlock events triggers**

## 4. Vehicle Modules

This section covers the vehicle related modules and settings.

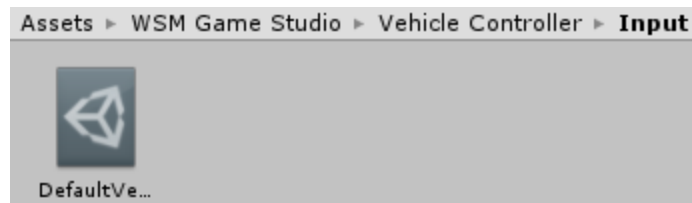

### 4.1. Vehicle Input

This component is responsible for handling player input for all vehicle specific behaviours. It holds a reference to the Default Vehicle Input Settings file, which contains the keyboard key configurations for driving your dump truck.

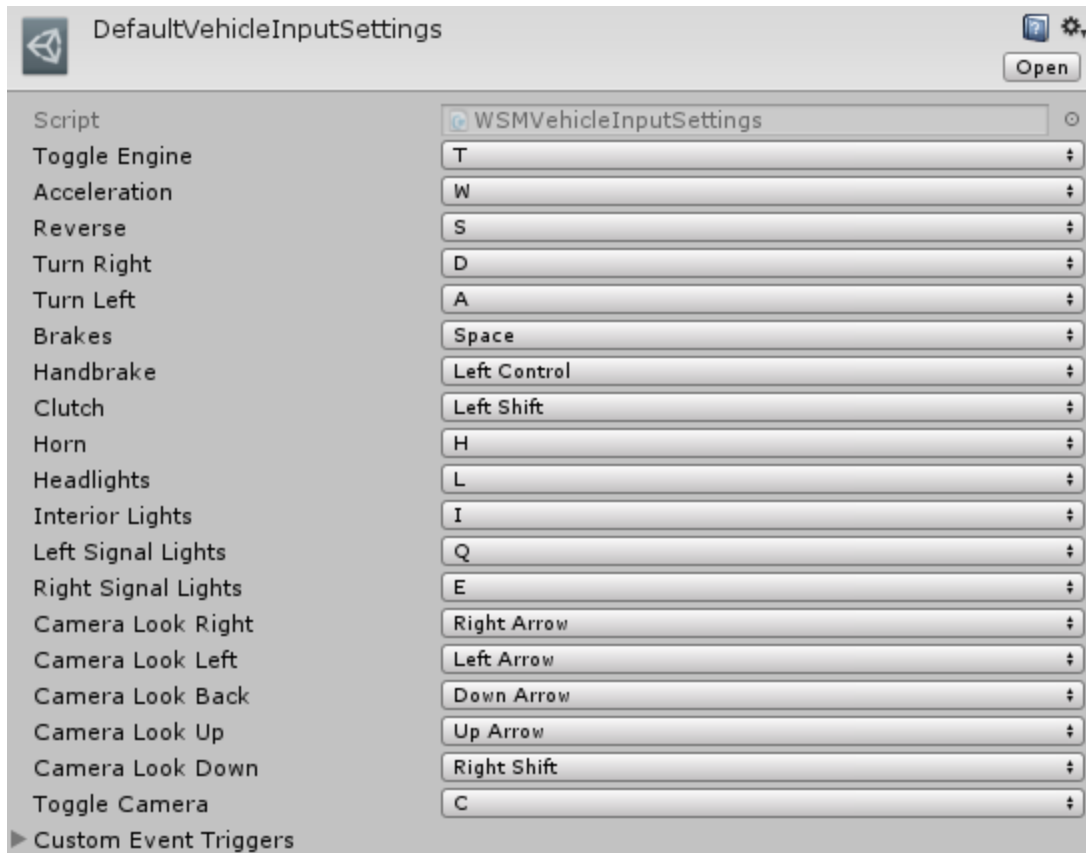

**Figure: Vehicle Player Input**

The Default Vehicle Input Settings file is located under the “WSM Game Studio ► Vehicle Controller ► Input” folder.

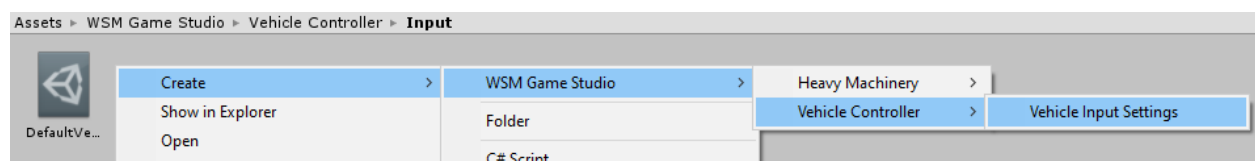

**Figure: Vehicle Player Input Location**

By selecting this file, you can see and customize the input keys used to control your vehicle.

**Figure: Vehicle Input Settings**

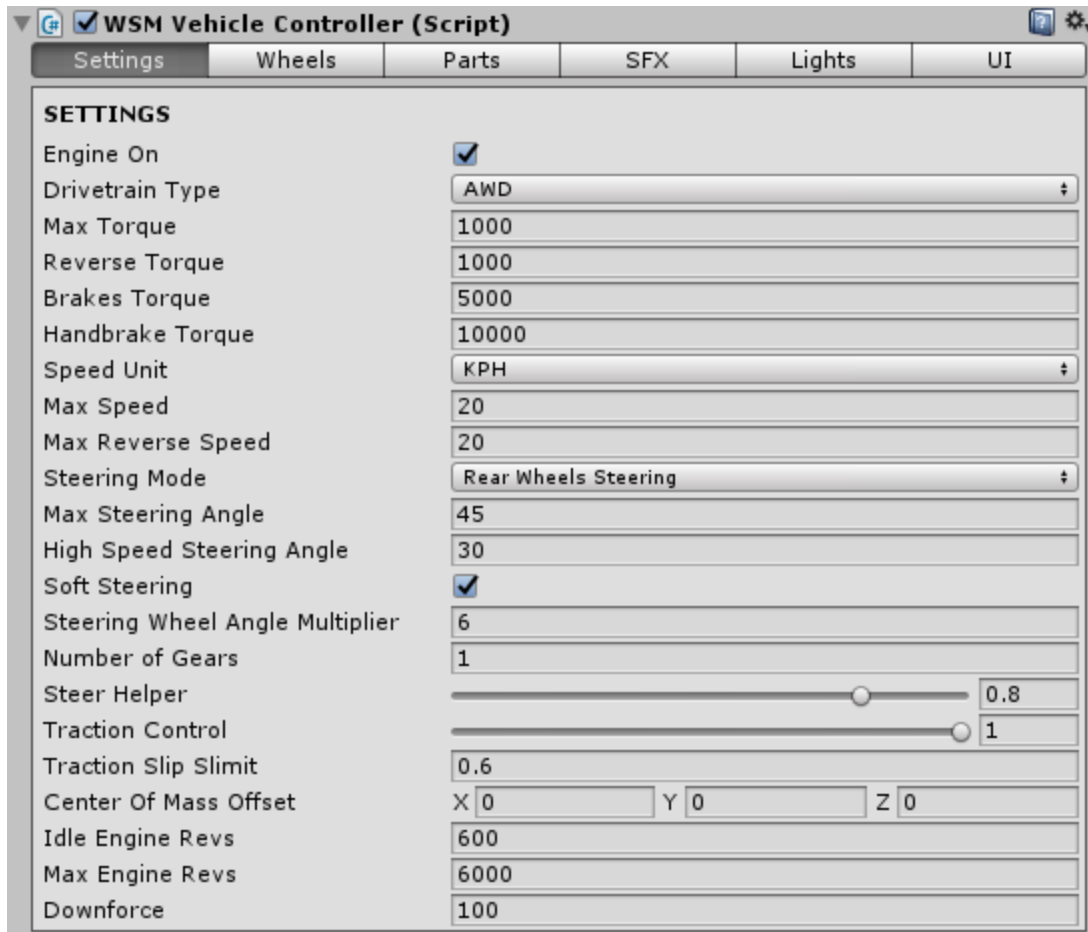

You can also create a new custom input settings by right-clicking on your project and using the Unity Creation menu: “Create ► WSM Game Studio ► Vehicle Controller ► Vehicle Input Settings”.

**Figure: Creating a new Vehicle Input Settings**

## 4.2. Vehicle Controller

This component is responsible for controlling vehicle related behaviours and vehicles physics.

**Figure: Vehicle Settings**

Most vehicle settings located here are very straightforward and use the same nomenclature as the corresponding real world counterpart. The most specific settings will be covered in this section.

**Note:** If you have any questions about any specific setting that was not covered in this section, feel free to email me about it (See [Contact Info & Support](#) section)

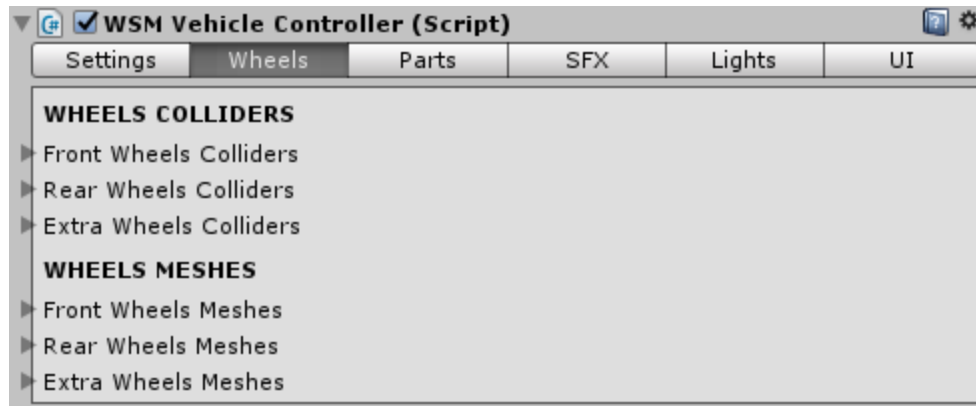

Figure: Vehicle Wheels

The Wheels tab holds references to all [Wheel Colliders](#) and Wheels Meshes. Front and rear wheel references are separated from each other. It was designed this way, so it would be possible to set up which wheels receive traction and which wheels are used for steering.

**Note:** Wheels traction is defined by the **Drivetrain Type** property and steering is defined by the **Steering Mode** property (Settings tab)

If your vehicle has more than four wheels, you can also use the Extra Wheels collections to assign the additional wheels references.

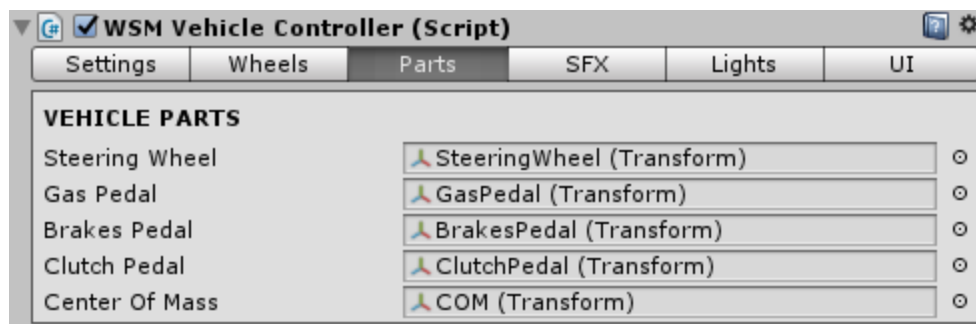

Figure: Vehicle Parts

The Parts tab holds references to all vehicles moving parts. If your vehicle has an open cabin or if your game supports cabin interior view, this is where you can set a reference to your steering wheel and pedals.

The rotation ratio between the wheels and the steering wheel is defined by the **Steering Wheel Angle Multiplier** property (Settings tab).

The Center of Mass reference is used to visualize the vehicle center of mass position. Which can be adjusted by the **Center of Mass Offset** property (Settings tab).

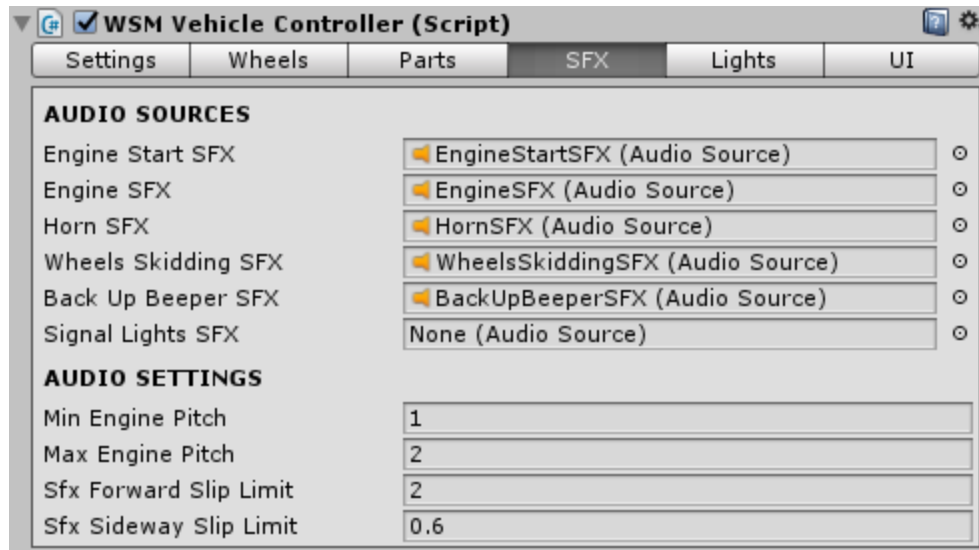

Figure: Vehicle SFX

The SFX tab holds references to the vehicle's [Audio Sources](#). Audio settings are also located here.

The min and max engine pitch properties are used to simulate engine revving and gear switching sounds. The slip limit properties are used to adjust when the wheel skidding SFX should be played.

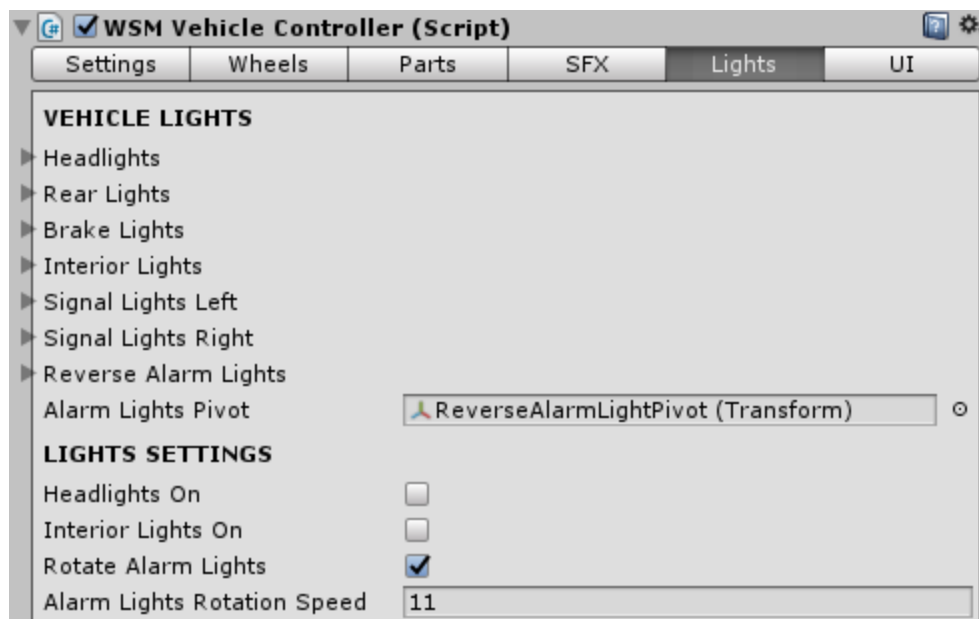

Figure: Vehicle Lights

The Lights tab holds references to the vehicle's lights. Lights settings are also located here.

**Note:** Alarm lights rotation refers to the **Reverse Alarm Lights**. Some trucks and other heavy vehicles usually have rotating lights to warn pedestrians, besides the backup beeper sound.

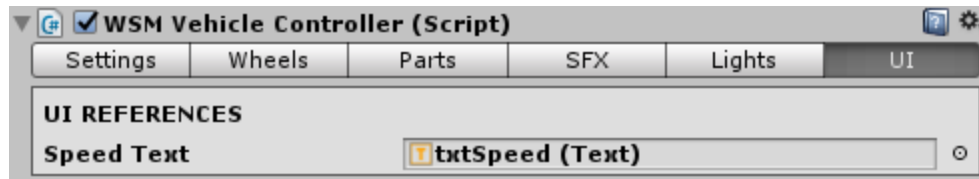

Figure: Vehicle UI

The UI tab holds a reference to the vehicle related UI. For now, it contains only an option for outputting the current vehicle speed.

**Note:** You can choose KPH and MPH by changing the **Speed Unit** property (Settings tab).

### 4.3. Vehicle Camera

A simple vehicle camera is also included in this package. The following camera types are currently supported:

- TPS (Third Person)
- FPS (First Person)
- Top Down

Also, runtime camera toggle can be enabled or disabled here. (See [Vehicle Input](#) section for more details on camera input keys)

**Note:** The Vehicle Camera component only shows the settings of the currently selected camera type.

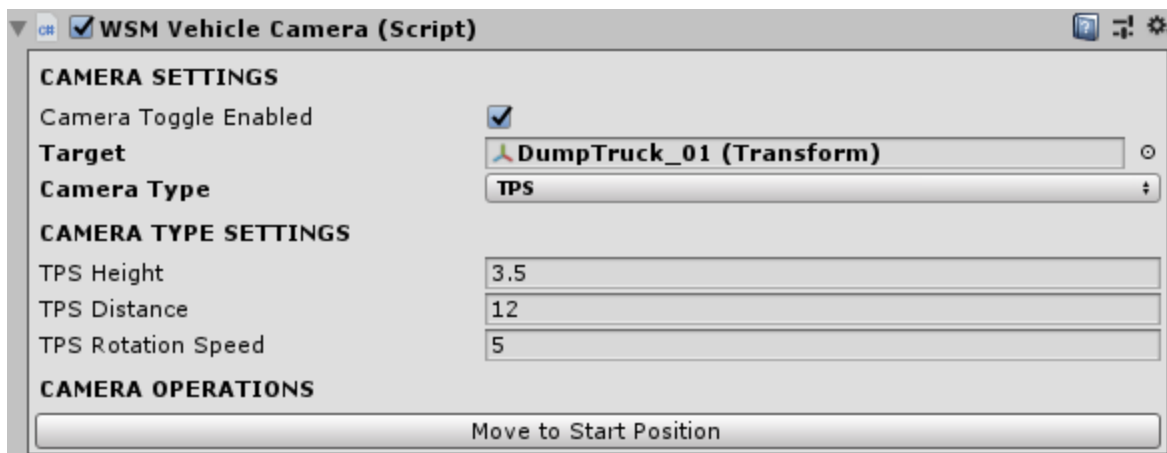

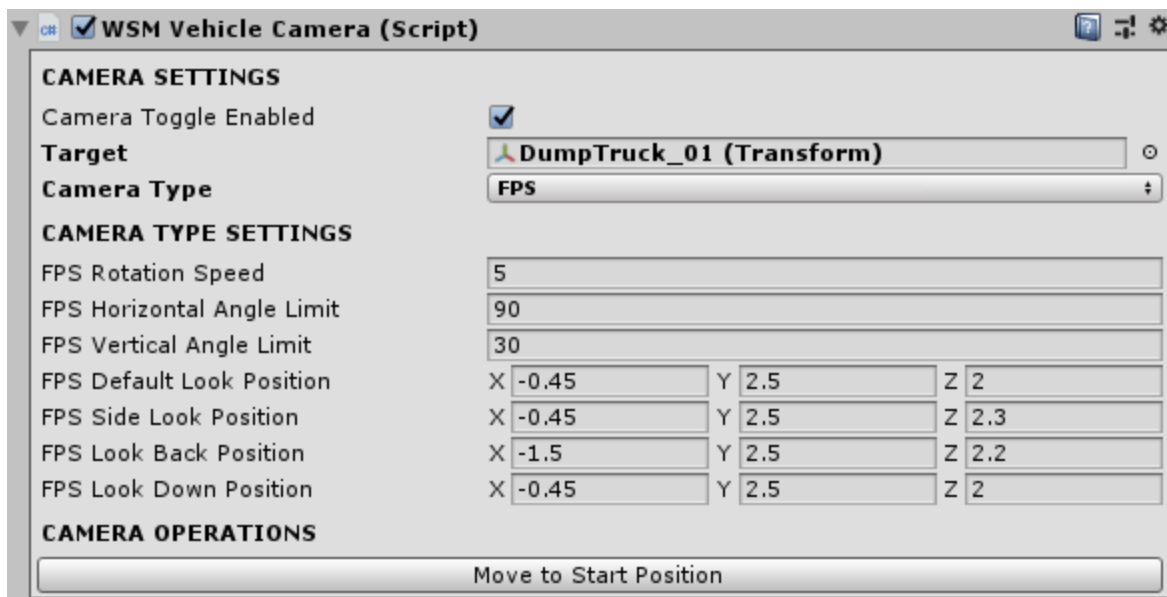

Figure: TPS Camera Settings

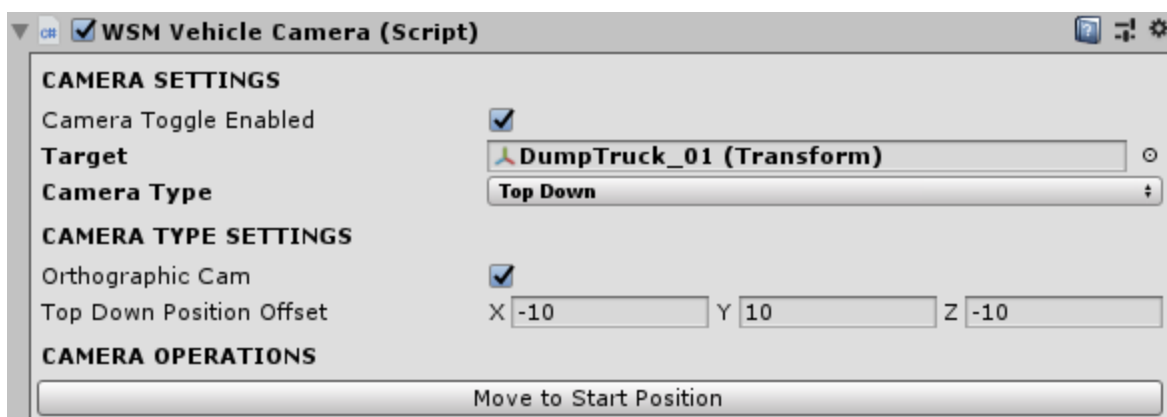

You can adjust the height, distance and speed of the TPS camera. While the TPS camera is selected, you can also look left, right or backwards.

**Figure: FPS Camera Settings**

While the FPS camera is selected, you can look left, right, backwards, up and down. You can also change the camera position for each look direction. This allows you to simulate some interesting behaviours, like putting the head out of the window when looking backwards.

**Note:** The position shift technique was used to look at the rear of the dump truck while reversing (FPS camera).

**Figure: Top Down Camera Settings**

While the Top Down camera is selected, you can adjust the camera position offset and choose between orthographic or perspective camera projection.

**Tip:** Use the *Move to Start Position* operation to preview the camera position after adjusting the settings.

## 5. Additional Info

### 5.1. Customization

This package includes a simple dump truck model for sample purposes. More dump truck models may be included in the future and/or sold separately as extensions ([Here](#)).

If you have your own models, it is possible to create custom dump trucks by using the sample prefabs as a starting point and replacing the models using the Unity Editor default prefab editing workflow.

Just make sure your custom dump truck main body, dump bed, tailgate, doors, cylinders and wheels models are separated from each other as shown in the sample image below.

**Figure: Default Dump Truck Models**

### 5.2. Dump Truck Carrying Weight Capacity

As in real life, the dump trucks included on this asset have limited carrying weight capacity. Trying to transport cargo above this limit will increase the vehicle overall weight, making it harder to drive it around.

Rule of thumb is, a dump truck cannot carry cargo heavier than itself.

For this asset, the recommended rigidbody mass value for cargo must not exceed 40% of the dump truck mass.

Since sample prefabs are set to 10000 rigidbody mass, the maximum recommended mass sum for cargo is 4000.

**Note:** Due to Unity physics engine limitations, the dump truck rigidbody cannot exceed 10000 mass. Rigidbodies with mass greater than 10000 may cause unpredictable physics behavior on Unity games.

## 5.3. Rear Steering Vehicle Guidelines

The Vehicle Controller included in this package does support rear wheel steering vehicles.

Rear wheel steering vehicles, like forklifts for example, tend to easily [oversteer](#) on higher speeds which can result in undesired vehicle fishtailing.

To avoid [fishtailing](#), increase the Steer Helper property value until your vehicle reaches the desired trade-off between realism and control.

Since vehicles are [nonlinear systems](#), the optimal Steer Helper value will change accordingly to your vehicle aerodynamics, center of mass and settings. It's recommended to test each vehicle and adjust the settings until the desired behaviour is achieved.

## 6. License

By purchasing this asset you are allowed to use it for unlimited games and/or 3D projects (like animations, simulation softwares, etc). Both personal and commercial use.

You are **NOT** allowed to resell or distribute the assets components individually or as part of another asset package (including, models, scripts, etc).

## 7. Contact Info & Support

If you have any questions, need support or have some business inquiries, feel free to get in touch.

The best way to reach us is by email on [wsmgamestudio@gmail.com](mailto:wsmgamestudio@gmail.com).
